LEVEL 1 CAMBRIDGE NATIONAL IN SCIENCE

R072/01/I How scientific ideas have developed

INSERT

Duration: 1 hour

INSTRUCTIONS TO CANDIDATES

- This Insert contains the case study required to answer Question 1. Question 1 accounts for 25% of the total marks.

INFORMATION FOR CANDIDATES

- This document consists of 4 pages. Any blank pages are indicated.

INSTRUCTION TO EXAMS OFFICER/INVIGILATOR

- Do not send this Insert for marking; it should be retained in the centre or recycled. Please contact OCR Copyright should you wish to re-use this document.

The Organisation Man

Carl Linnaeus (1707–1778) was interested in plants and became a great botanist. He sorted all the species of plants and animals known in his day in a systematic and organised way. The simplicity and logic of his classification system (his taxonomy) made natural history accessible to amateurs, perhaps starting the Victorian passion for nature.

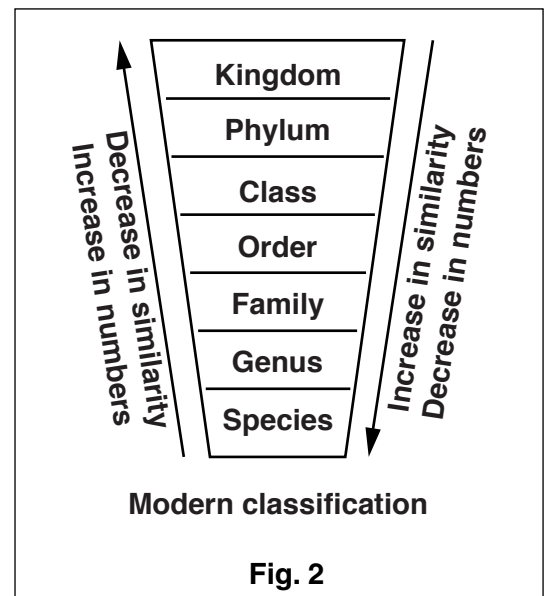

Before Linnaeus, taxonomy was uncoordinated. Even the commonest species had complex names. The tomato plant, for example, was called *Solanum caule inermi herbaceo, foliis pinnatis incisives*. This means ‘the solanum with the smooth stem which is herbaceous and has incised pinnate leaves’.

Linnaeus knew nothing of DNA or other modern developments. He lived in Sweden and he decided to apply the social hierarchy of his day, with kingdoms, counties, towns and villages, to the natural world. He slotted plants and animals into a framework of categories, as shown in **Fig. 1**. He decided to call each living thing by just two Latin names, representing **genus** and **species**. This innovation was known as binomial nomenclature. It has proved to be Linnaeus' greatest gift to science. Any time *Homo sapiens* (human being) mention *Felis domestica* (house

cat) or *Lycopersicon esculentum* (tomato plant), Linnaeus' naming system is being used. From the many competing ways to name species, he made a single, universal scientific language.

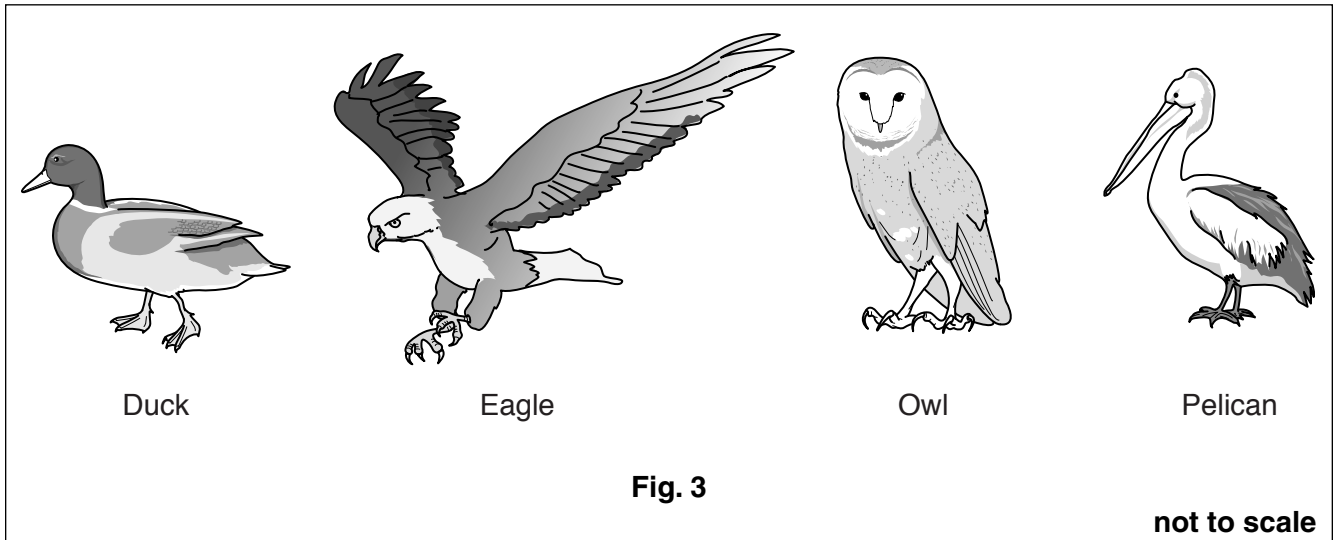

Linnaeus liked to say, “God created, but Linnaeus organised.” In 1735 he published an 11-page booklet called ‘*Systema naturae*’. This split the world into three Kingdoms: animals, plants and minerals. He kept adding to his booklet throughout his life, and when the 13th edition was published in 1770, it had grown to 3000 pages. His classification system was so easy to use that scientific discoveries became much more common. However, the number of species which have been discovered mean that no one person could ever hope to create such a complete record working alone.

Classifying plants:

Linnaeus had to find categories for the many forms of life. In classifying plants, Linnaeus chose to focus on sexual characteristics. He placed plants into **classes** according to the number, length and features of their stamens (male parts), and into **orders** according to their female parts. The approach was not popular. His colleagues objected to his descriptions of plants and some refused to use his system.

Classifying animals:

For animals, Linnaeus used different features. He grouped mammals according to their teeth, toes and teats; fish by their fin bones; insects by their wings; and birds by their feet and their beaks (**Fig. 3**).

Linnaeus knew that his categories for plants and animals were arbitrary and his classification no more than a rough attempt at finding nature's pattern. Despite their shortcomings, Linnaeus' names for about 12 000 organisms he examined over the course of his life became the starting point for biological classification.

Linnaeus, Lamarck and Darwin:

As Linnaeus travelled, he discovered and named over 100 new species. He wondered if he could cultivate crops from all over the world where he lived in Sweden. Although he lived long before Lamarck, Linnaeus believed that organisms would rapidly become adapted to a new environment and grow successfully.

Ultimately, Linnaeus was mistaken in his view that plants will adapt to grow anywhere. He reluctantly came to accept this after most of his transplants failed. He was also wildly wrong about the number of living species. He thought there might be around 40 000 altogether. Estimates today range from 10 million to 100 million, most of which are microscopic.

When Darwin published his *On the Origin of Species*, he stressed the importance of biodiversity. Species could come into being and become extinct as a result of environmental changes. Many years earlier, Linnaeus had written, "I do not know how the world could persist gracefully if but a single animal species were to vanish from it."

**Copyright Information**

OCR is committed to seeking permission to reproduce all third-party content that it uses in its assessment materials. OCR has attempted to identify and contact all copyright holders whose work is used in this paper. To avoid the issue of disclosure of answer-related information to candidates, all copyright acknowledgements are reproduced in the OCR Copyright Acknowledgements Booklet. This is produced for each series of examinations and is freely available to download from our public website (www.ocr.org.uk) after the live examination series.

If OCR has unwittingly failed to correctly acknowledge or clear any third-party content in this assessment material, OCR will be happy to correct its mistake at the earliest possible opportunity.
